

Cellular Automata

- another example of systems where simple short-range rules give rise to complex emergent behavior

<https://www.wolframscience.com/nks/notes/6-8--structures-in-the-game-of-life/>

Cellular Automata

A *cellular automaton* has four key elements:

- a collection of cells arranged in a grid
 - there can be any (finite) number of dimensions
- each cell has a state
 - there are a finite number of possible states
- each cell has a neighborhood
 - typically all cells adjacent to that cell
- a ruleset defining how a cell's state changes from one generation to the next

Elementary CAs

- the simplest grid is a 1D line of cells

- the simplest set of states is two states – 1/0, on/off, true/false, alive/dead

- the simplest neighborhood is the two immediate neighbors (left and right)

Elementary CAs

- the ruleset defines how a cell's state changes from one generation to the next

Elementary CAs

- the evolution over time can be shown by drawing each generation on successive rows, using black for 1 and white for 0

gen 0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0
gen 1	0	0	0	0	0	0	0	1	0	1	0	0	0	0	0	0	0
gen 2	0	0	0	0	0	0	1	0	0	0	1	0	0	0	0	0	0
gen 3	0	0	0	0	0	1	0	1	0	1	0	1	0	0	0	0	0
gen 4	0	0	0	0	1	0	0	0	0	0	0	1	0	0	0	0	0
gen 5	0	0	0	1	0	1	0	0	0	0	0	1	0	1	0	0	0
gen 6	0	0	1	0	0	0	1	0	0	0	1	0	0	0	1	0	0
gen 7	0	1	0	1	0	1	0	1	0	1	0	1	0	1	0	1	0
gen 8	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Elementary CAs

Elementary CAs

Different rulesets lead to different kinds of behaviors.

- class 1 – uniformity
 - after enough time, every cell ends up in the same state
- class 2 – repetition
 - after enough time, cell states cycle through a repeating pattern
- class 3 – random
 - no discernable pattern
- class 4 – complexity
 - repetitive patterns appear randomly

2D Cellular Automata

- the line of cells becomes a grid of cells
- the neighborhood contains all adjacent cells

1	0	1	1	0	1	0	0	1
1	1	0	1	1	1	0	1	1
1	1	1	0	0	1	0	1	0
0	1	1	1	0	1	1	0	1
1	0	0	1	0	1	0	1	1
0	1	1	0	0	0	1	1	0

Conway's Game of Life

- John Conway, 1937-2020
 - British mathematician
 - known for
 - the Game of Life
 - combinatorial games (sprouts, phutball, Conway's soldiers, angels and devils)
 - the Doomsday algorithm for determining the day of the week for a given date
 - results in a variety of other areas (geometry, geometric topology, group theory, number theory, algebra, analysis)

Conway's Game of Life

1	0	1	1	0	1	0	1
1	1	0	1	1	1	0	1
1	1	1	0	0	1	0	1
0	1	1	1	0	1	1	1
1	0	0	1	0	1	0	1
0	1	1	0	0	0	1	1

Rules –

- a living cell (state 1) dies (state 0) if –
 - it has four or more living neighbors (overpopulation)
 - it has one or fewer living neighbors (loneliness)
 otherwise it remains alive
- a dead cell (state 0) comes to life (state 1) if –
 - it has exactly three living neighbors
 otherwise it remains dead

Conway's Game of Life

- a living cell (state 1) dies (state 0) if –
 - it has four or more living neighbors (overpopulation)
 - it has one or fewer living neighbors (loneliness)
- a dead cell (state 0) comes to life (state 1) if –
 - it has exactly three living neighbors

Common patterns –

- still lifes
 - fixed patterns which do not change from generation to generation
- oscillators
 - patterns which return to their initial state after a finite number of generations
- spaceships
 - patterns which move across the grid

Fire Simulation

- 2D cellular automaton
- three cell states
 - 0 (empty) – the cell is empty ground or contains a burnt tree
 - 1 (tree) – the cell contains a tree that is not burning
 - 2 (burning) – the cell contains a tree that is burning
- the neighborhood is only the cells directly north, south, east, west
- rules
 - if a cell is empty, it remains empty
 - if a cell is burning, it becomes empty
 - (it only takes one time step to fully burn a tree)
 - if a cell contains a tree and has at least one burning neighbor, it catches fire with a probability p_{catch}
 - otherwise the cell remains in the same state

Fire Simulation

Implementing Elementary CAs

111	110	101	100	011	010	001	000
↓	↓	↓	↓	↓	↓	↓	↓
0	1	0	1	1	0	1	0

- a ruleset can be implemented with an array
 - assume the neighborhoods are always listed in the order shown (111, 110, 101, ...)

```
boolean[] ruleset = { false, true, false, true, true,
                     false, true, false };
```

- this *initializer list* syntax declares an array variable `ruleset`, creates 8 slots, and initializes the slots all in one step

Implementing Elementary CAs

1	0	1	0	1	1	1	0	0	1
---	---	---	---	---	---	---	---	---	---

- a line of cells becomes an array
- two possible states means the base type is boolean (`true=1`, `false=0`)
- initialization options
 - set the middle cell to `true` and the rest to `false`
 - initialize each cell randomly (`true` or `false`)

```
if ( random(1.0) < 0.5 ) { ... }
else { ... }
```

Implementing Elementary CAs

- computing the next generation

For every cell in the array:

1. Take a look at the neighborhood states: left, middle, right.
2. Look up the new value for the cell state according to a ruleset.
3. Set the cell's state to that new value.

this code has bugs!
do not use without
modifications!

```
for ( int i = 0 ; i < cells.length ; i = i+1 ) {
    boolean left = cells[i-1];
    boolean middle = cells[i];
    boolean right = cells[i+1];

    boolean newstate;
    if ( left && middle && right ) { newstate = ruleset[0]; }
    else if ( left && middle && !right ) { newstate = ruleset[1]; }
    else if ( left && !middle && right ) { newstate = ruleset[2]; }
    else if ( left && !middle && !right ) { newstate = ruleset[3]; }
    else if ( !left && middle && right ) { newstate = ruleset[4]; }
    else if ( !left && middle && !right ) { newstate = ruleset[5]; }
    else if ( !left && !middle && right ) { newstate = ruleset[6]; }
    else if ( !left && !middle && !right ) { newstate = ruleset[7]; }
    cells[i] = newstate;
}
```

111	110	101	100	011	010	001	000
↓	↓	↓	↓	↓	↓	↓	↓
0	1	0	1	1	0	1	0

Implementing Elementary CAs

- wrinkle #1 – edge cases

```
for ( int i = 0 ; i < cells.length ; i = i+1 ) {
    boolean left = cells[i-1];
    boolean middle = cells[i];
    boolean right = cells[i+1];
    ...
}
```

0	1	2	3	...	cells.length-1
1	0	1	0	1	1
0	0	1	0	0	1

– what happens when i is 0? or cells.length-1?

- options for handling edge cases

- edges remain constant
 - don't update cells[0] and cells[cells.length-1]
- edges wrap around
 - left for cells[0] is cells[cells.length-1]
 - right for cells[cells.length-1] is cells[0]
- define special neighborhoods and rules

Implementing Elementary CAs

- wrinkle #2 – inconsistent update

```
for ( int i = 0 ; i < cells.length ; i = i+1 ) {
    boolean left = cells[i-1];
    boolean middle = cells[i];
    boolean right = cells[i+1];

    boolean newstate;
    ...
    cells[i] = newstate;
}
```

111	110	101	100	011	010	001	000
↓	↓	↓	↓	↓	↓	↓	↓
0	1	0	1	1	0	1	0

1	0	0	0	1	1	0	0	1
			0	0				

neighborhood is now a mixture of
the current generation and the new
generation

- fix: use a separate array for the next generation

```
{
    boolean[] newcells = new boolean[cells.length]; // same size as cells
    for ( int i = 0 ; i < cells.length ; i = i+1 ) {
        boolean left = cells[i-1];
        boolean middle = cells[i];
        boolean right = cells[i+1];
        ...
        newcells[i] = newstate; // save the new state in the next generation
    }
    cells = newcells; // replace the current generation with the new
}
```

Drawing Elementary CAs

- each generation is drawn on a separate row

gen 0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0
gen 1	0	0	0	0	0	0	0	1	0	1	0	0	0	0	0	0	0
gen 2	0	0	0	0	0	0	1	0	0	0	1	0	0	0	0	0	0
gen 3	0	0	0	0	0	1	0	1	0	1	0	1	0	0	0	0	0
gen 4	0	0	0	0	1	0	0	0	0	0	0	0	1	0	0	0	0
gen 5	0	0	0	1	0	1	0	0	0	0	0	1	0	1	0	0	0
gen 6	0	0	1	0	0	0	1	0	0	0	1	0	0	0	1	0	0
gen 7	0	1	0	1	0	1	0	1	0	1	0	1	0	1	0	1	0
gen 8	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

- is this making choices, repetition, or just a series of steps?
 - repetition

Drawing Elementary CAs

- what is repeated?
 - drawing a row
- what differs from one row to the next?
 - the current generation
 - y coordinate
- how do we start?
 - initialize gen 0 with random values
 - y = 0 (top of row)
- how do things change?
 - compute the next generation
 - y = y + height of row
- when do we keep going?
 - as long as the current row fits in the window (repeat-as-long-as pattern)

gen 0	0	0	0	1	0	0	0	1	0	0	0	0	0	0	0
gen 1	0	0	0	0	0	0	0	1	0	1	0	0	0	0	0
gen 2	0	0	0	0	0	1	0	0	0	1	0	0	0	0	0
gen 3	0	0	0	0	1	0	1	0	1	0	0	0	0	0	0
gen 4	0	0	0	0	1	0	0	0	0	0	0	1	0	0	0
gen 5	0	0	0	1	0	1	0	0	0	0	0	0	0	0	0
gen 6	0	0	1	0	0	0	1	0	0	0	0	0	0	1	0
gen 7	0	1	0	1	0	0	1	0	1	0	1	0	1	0	0
gen 8	1	0	1	0	0	0	0	0	0	0	0	0	0	0	1

2

Drawing Elementary CAs

- drawing one row
 - 0 0 0 1 0 1 0 0 0 0 0 1 0 1 0 0 0
- what is repeated?
 - drawing one cell
- what differs from one cell to the next?
 - the slot in the array
 - the x coordinate
- how do we start?
 - slot 0
 - x = 0 (left side of rect)
- how do things change?
 - increment slot
 - x = x + width of cell
- when do we keep going?
 - for each slot of the array (going-through-an-array loop)

natureofcode.com/cellular-automata/

3

Implementing 2D CAs

- a grid corresponds to a 2D array
 - rows and columns
- declaring a 2D array variable

```
boolean[][] cells;
```
- creating a 2D array

```
cells = new boolean[rows][columns];
```
- going through every slot of a 2D array
 - nested loops

```
for ( int i = 0 ; i < cells.length ; i = i+1 ) { // rows
    for ( int j = 0 ; j < cells[i].length ; j=j+1 ) { // columns
        cells[i][j] = ...;
    }
}
```

	0	1	2	3	4	5	6	7	8
0	1	0	1	1	0	1	0	0	1
1	1	1	0	1	1	1	0	1	1
2	1	1	1	0	0	1	0	1	0
3	0	1	1	1	0	1	1	0	1
4	1	0	0	1	0	1	0	1	1
5	0	1	1	0	0	0	1	1	0

natureofcode.com/cellular-automata/

Implementing 2D CAs

- drawing a 2D CA
 - for each slot of the array, draw a black- or white-filled rect
- for each slot of the array –

```
for ( int i = 0 ; i < cells.length ; i = i+1 ) {
    for ( int j = 0 ; j < cells[i].length ; j=j+1 ) {
        ...
    }
}
```
- what changes from one slot to the next?
 - rows (i) – y coordinate
 - columns (j) – x coordinate

	0	1	2	3	4	5	6	7	8
0	1	0	1	1	0	1	0	0	1
1	1	1	0	1	1	1	0	1	1
2	1	1	1	0	0	1	0	1	0
3	0	1	1	1	0	1	1	0	1
4	1	0	0	1	0	1	0	1	1
5	0	1	1	0	0	0	1	1	0

natureofcode.com/cellular-automata/

Implementing 2D CAs

- accessing neighbors

i-1,j-1	i-1,j	i-1,j+1
i,j-1	i,j	i,j+1
i+1,j-1	i+1,j	i+1,j+1

	0	1	2	3	4	5	6	7	8
0	1	0	1	1	0	1	0	0	1
1	1	1	0	1	1	1	0	1	1
2	1	1	1	0	0	1	0	1	0
3	0	1	1	1	0	1	1	0	1
4	1	0	0	1	0	1	0	1	1
5	0	1	1	0	0	0	1	1	0

naturecode.com/cellular-automata/

Implementing the Game of Life

- counting the number of living neighbors

i-1,j-1	i-1,j	i-1,j+1
i,j-1	i,j	i,j+1
i+1,j-1	i+1,j	i+1,j+1

```
int numliving = 0;
if ( cells[i-1][j-1] ) { numliving = numliving+1; }
if ( cells[i-1][j] ) { numliving = numliving+1; }
if ( cells[i-1][j+1] ) { numliving = numliving+1; }
if ( cells[i][j-1] ) { numliving = numliving+1; }
if ( cells[i][j+1] ) { numliving = numliving+1; }
if ( cells[i+1][j-1] ) { numliving = numliving+1; }
if ( cells[i+1][j] ) { numliving = numliving+1; }
if ( cells[i+1][j+1] ) { numliving = numliving+1; }
```
